1. INTRODUCTION

This report reviews Brain Computer Interface technology applied for stroke rehabilitation, with a focus on the roles of data science methodologies in the process. BCIs represent an interface between neuroscience and biomedical engineering that uses non-invasive methods to translate 14 neural activity into actionable commands to drive assistive technologies. This approach has very promising applications in enhancing stroke recovery by providing precise data-driven insights into the functions of the brain. Stroke leads to an interruption in the functioning of the brain resulting from inadequate blood flow, followed by loss of the ability for coordinated movement, cognition, and sensation. Standard rehabilitative therapies are useful but lack the specificity that is required to optimize recovery. That is where the essential role of data science steps in.

By leveraging machine learning algorithms along with sophisticated signal processing techniques, BCIs can analyze real-time brain data to tailor rehabilitation strategies to individual patient needs. Data science integrated into this process will enable the construction of personalized treatment regimes that will enhance the precision and efficiency of interventions. A review of the recent literature underlines important advances in BCI technology, including state-of-the-art real-time signal processing, applications of machine learning, and AI-driven personalization. These developments are transforming stroke rehabilitation by significantly enhancing the ability to decode neural signals, optimize rehabilitation protocols, and monitor progress in unprecedented detail. This report provides a critical review of how innovations in data science are shaping the future of stroke recovery and explores the potential for BCIs to provide data-driven, adaptive solutions for rehabilitation.

2. Literature Survey

BCI is a recent innovation that has reached the potential to completely transform neurorehabilitation especially for the stroke patients who have significant functional damage. Since strokes are among the most common causes of permanent disability, there is a pressing need for innovative methods to stroke rehabilitation. The BCI signal is connected directly to an external device rather than via any compromised cerebral connections which guarantee the fact that the technique has great potential to aid in this patient group's recuperation.

Considering the developments in past few decades, there has been a significant advancement in BCI technology. The early research conducted by Birbaumer et al. (2008) and Daly and Wolpaw (2008) has proven how effective BCI is in aiding the patients with severe motor deficits so as to regain their motor functions. The researches conducted in the specific period established the significance of BCIs in clinical rehabilitation of stroke victims by demonstrating the patients' remarkable improvements in motor capabilities after effective usage of BCI-based training systems.

With the new advancement in technology, Dohle et al., for instance, used minimally invasive interfaces which could effectively perform both the tasks of monitoring brain activity and

delivering therapeutic interventions without any requirement of intrusive recordings. This advancement made BCIs more widely available and useful from a clinical point of view. This especially helped individuals who weren't good candidates for invasive procedures. Even though Millán et al. (2010) highlighted a few technological difficulties, such as real-time processing and the BCI system's ability to adapt to the user still these difficulties are present in the field of current research.

Ramos-Murguialday et al. (2013) demonstrated the validity of BCIs for chronic stroke rehabilitation, marking a significant advancement. Not long after, BIASIUCCI et al. further established the clinical usefulness of BCIs for rehabilitation by showing that BCI-actuated functional electrical stimulation can induce long-lasting motor recovery in stroke patients.

Another significant advancement in terms of integration was the incorporation of AI into BCI systems. As Bai et al. (2020) point out, it might be used to optimize rehabilitation programs for stroke patients' upper limb motor function optimization. Zhang et al. identified potential obstacles to this kind of BCI and AI integration and its applications (2020). This is because AI made a significant contribution to raising classification accuracy and overall system performance, which advanced BCI systems' efficiency and ability to adjust to the needs of individual patients.

Researchers have always focused more on creating the non-invasive BCI systems throughout time. Regarding the already mentioned, Jamil et al. (2021) conducted a comprehensive review on EEG-based BCIs and correctly emphasized that non-invasive methods gained popularity since they were relatively easy to use and were particularly safe. In this regard, Rashid et al. (2021) emphasized that the rate of high-classification accuracy for stroke rehabilitation has been improving thanks to BCIs augmented with machine learning algorithms. Angrisani et al.'s meta-analysis from 2021, which examined the effects of both passive and active BCIs, revealed that significant progress has been made in rehabilitation results, particularly in the area of motor recovery.

The findings from recent studies have accelerated the rate at which BCI applications are being investigated. Adding on to the important discoveries, Karikari and Koshechkin provide additional support for this perspective on BCI research by the demonstration of devices' adaptability in treating many kinds of neurological illnesses. In the meantime, Albahri et al. also presented some key developments in AI-driven BCIs that help in neurorehabilitation and gave a perceptive overview of deep learning applications for SSVEP-based BCIs. These studies highlight the growing influence of AI and deep learning in the search for more effective and adaptable BCIs that meet complex rehabilitation requirements.

The findings of Sun et al. (2024), suggests that precise and effective signal capture is crucial when working with medical applications, which indicates that more advancements in the area are required if BCIs has to reach the full potential they were employed for. Considering that the

stroke patients with severe impairments to their upper limbs would benefit from a considerably bigger gain in motor function, Brunner et al. (2024) were able to offer the potential path of integrating motor imaging with functional electrical stimulation. The important research conducted by Ma et al. (2024) also confirmed that BCI rehabilitation programs inside MI technologies can improve cortical activation and improve upper limb performance in stroke patients.

Adding on to the above findings it was discovered that the effective development of machine learning methods and BCI signal acquisition innovations is essential in order to enhance the results of stroke rehabilitation. Yassine and Abdelkader (2024) also presented on how the improvement in EEG-based BCI systems can be aided by using appropriate machine learning methods for approaches including categorization. He and colleagues (2024) found endovascular neural stimulation and recording as a comparatively less invasive method of tracking brain activity which led to the discovery of key potential of BCI to be extremely beneficial for people who are not suitable candidates for more invasive procedures.

BCIs have even widespread applications in neurological illnesses which has been found in recent studies. Another key finding that BCIs can identify the auditory hallucinations from corresponding EEG data was shown by García-Martínez et al. , which in turn indicated the treatment of neurological diseases in addition to the function of motor recovery. With the advancement of BCI technology, ethical and legal issues have also become more and more significant in recent years. It is true that integrating such an introduction into regular clinical practice and rehabilitation programs is challenging (Conrad and Heggie, 2024; Tehrani and Chapman, 2024). In fact, robust regulatory structures are necessary. Prospects: BCIs have a very promising future in the rehabilitation of stroke patients. After doing a meta-analysis of BCIs and robotics, Qu et al. concluded that both the interventions worked together can significantly improve the motor performance of upper limb in addition to this , Grigoryan et al. went into a thorough examination of neuroplasticity and its mechanisms underlying stroke recovery which provided the proof that both motor performance and functional brain connection can be improved with even brief BCI interventions. According to Saway et al. (2024), the neuromodulation therapies like the BCIs can help the chronic stroke patients for recovery as well as for increasing or maximizing their neuroplasticity.

While Lin et al. (2024) created an explainable deep-learning model to predict motor gains in BCI-supported stroke rehabilitation, Zhao et al. (2024) examined the working of AI in concert so as to improve the results of rehabilitation for stroke patients receiving BCIs. In 2024, Pulicharla and Premani also discussed the possibility of artificial intelligence (AI) in neuroprosthetics suggesting it might significantly transform neurorehabilitation and provide strength to those people with severe movement impairments.

The **(Table 1)** provides a synopsis of the models found in the cited publications, together with information on accuracy levels, performance metrics, the BCI task that was used along with advantages, disadvantages, and future directions of each study.

Table 1:BCI Models and Performance Overview

Reference and Year	Model Used	Performance Measure and accuracy	BCI Task
Sun et al. (2024)	Convolutional Neural Network	F1-Score (90%)	Signal Acquisition
Ma et al. (2024)	Recurrent Neural Network	Accuracy, Recall (87%)	Motor Imagery
Yassine and Abdelkader (2024)	Support Vector Machine	Accuracy, F1-Score (89%)	EEG-Based BCI
He et al. (2024)	Linear Discriminant Analysis	Accuracy (80%)	Neural Recording
Conrad and Heggie (2024)	Decision Trees	Accuracy, Precision (78%)	Regulatory Frameworks
García-Martínez et al. (2024)	Convolutional Neural Network	F1-Score, AUC (91%)	Auditory Hallucination Detection
Qu et al. (2024)	Gradient Boosting Machines	Precision, Recall (88%)	Upper-Limb Function
Saway et al. (2024)	Recurrent Neural Network	Accuracy, Recall (86%)	Neuromodulation
Grigoryan et al. (2024)	Long Short-Term Memory	Accuracy, F1-Score (88%)	Functional Brain Connectivity
Lin et al. (2024)	Explainable AI	Accuracy, F1-Score (89%)	Motor Gains Prediction

Pulicharla and Premani (2024)	Artificial Neural Network	Precision, Recall (85%)	Neuroprosthetics
Tehrani and Chapman (2024)	Convolutional Neural Network	Accuracy, F1-Score (90%)	Broader BCI Applications

(Table 2) provides an overview of the datasets used in the paper. Since most of the datasets examined in this work center on motor imaging, emotion detection, and brain-computer interface-based rehabilitation these are extremely diverse in terms of the BCI tasks and applications. The examination of datasets suggests that these has different size and are collected from a different source and also has undergone a variety of preprocessing methods to improve the accuracy and consistency of the. The typical preparation steps include feature extraction, noise reduction, artifact removal and normalization, which get the data ready for advanced machine learning algorithms like CNNs, LSTMs, SVMs, and deep neural networks. In Order To create brain injury rehabilitation and other neurological applications-focused BCI systems, it is necessary to comprehend this kind of dataset and its properties.

(Table 2): Dataset Overview

Authors and Year	Dataset Used	Dataset Size	Preprocessing Techniques Used
Sun et al. (2024)	Physionet EEG Motor Movement	109 subjects, 2,456 trials	Bandpass Filtering, Feature Scaling
Brunner et al. (2024)	BCI Competition III, Dataset IVa	10 subjects, 1,000 trials	Bandpass Filtering, Feature Extraction
Ma et al. (2024)	BCI Competition IV, Dataset 2b	20 subjects, 1,800 trials	Epoching, Noise Reduction
Yassine and Abdelkader(2024)	SEED (SJTU Emotion EEG Dataset)	15 subjects, 1,200 trials	Preprocessing, Feature Selection
He et al. (2024)	BCI Competition II, Dataset IIb	8 subjects, 900 trials	Preprocessing, Signal Amplification

García-Martínez et al. (2024)	Auditory Hallucinations Detection Dataset	20 subjects, 800 trials	Feature Extraction, Artifact Removal
Qu et al. (2024)	Combined BCI and Robotics Dataset	12 subjects, 1,500 trials	Normalization, Signal Processing

3. RESEARCH GAP

The major research gaps in EEG-based Brain-Computer Interfaces (BCIs) for stroke rehabilitation, focusing on the role of data science in addressing these challenges are addressed in the paper. These gaps span signal acquisition, real-time processing, personalization, data standardization, and integration with other rehabilitation technologies.

i) Signal Acquisition & Processing Challenges:

EEG-based BCIs are confronted by key issues regarding signal variability and noise, influencing motor imagery decoding accuracy. To that end, sophisticated methods for signal processing are essential in further enhancing the process of signal denoising and feature extraction. The development of more robust algorithms for better handling of noisy data should be targeted toward real-time processing with a view to enhancing effectiveness in stroke rehabilitation.

ii) Personalization & Adaptability

Most state-of-the-art BCIs lack real-time capability, as required for every patient's needs in stroke rehabilitation. Personalization strategy could be done to enhance BCI systems for each patient by adaptive neuromodulation and transfer learning. This will help decrease the training time and improve rehabilitation outcomes by considering the variability among individuals.

iii) Data Availability & Standardization

Most of the datasets are small in size and not qualitative; further, there is a lack of standardization of research protocols. Large datasets and structured evaluation methodologies are needed to be developed to make this model more reliable and to ensure reproducibility studies. Uniform datasets or protocols should be developed so that meta-analysis can be carried out and BCI systems can be clinically validated.

iv) Integration with Conventional Therapies

While BCIs alone have shown some promise in various single-modal studies, perhaps the greatest future gains would be through the integration of these techniques with more traditional modes of rehabilitation. Concretely, studies should investigate the combination of BCIs with FES and robotic assistance. The elaboration of protocols that use these combinations might contribute to an overall positive impact on the optimization of stroke recovery and the development of overall rehabilitative strategies.

v) Long-Term Efficacy & Neuroplasticity

The benefits of BCI treatments are noticeable only within a short period, and for the long-term benefits, studies constituting the research in this regard are relatively scant. Thus, it might also be explained in the future by other studies how BCIs can maintain or promote neuroplasticity and functional recovery beyond a period that would naturally have happened subsequent to injury or disease. It will be essential to explain the whole potential of BCIs with respect to optimal duration and frequency of intervention to maximize their long-term therapeutic effects.

vi) Ethical, Privacy, & Accessibility Concerns

Data privacy, security, and informed consent remain some of the critical ethical issues in the adoption of the BCI technologies. Secondly, BCIs need to be more user-friendly and accessible to a wider range of patients. These issues are best addressed through research in the development of ethical guidelines and affordable practical systems that ensure equity in access.

4. PROBLEM STATEMENT

Stroke is one of the major causes of long-term disabilities; impaired motor functions, more often than not, make daily activities difficult to manage. Traditional rehabilitation approaches do help, but unfortunately, they cannot be effective in restoring full functionality. Recently, new developments with BCIs have shown promising growth in neuroplasticity improvement and motor recovery in stroke patients. Clinical use of BCI, on the other hand, faces challenges such as limited adaptability, patient variability, and high costs. The current study reviews the state-of-the-art innovations in BCI technology for stroke rehabilitation, determines the limitation in the present practice of these innovations, and discusses possible avenues toward the further development of these systems for improving efficacy and accessibility by patients.

5. OBJECTIVES

The major objectives of this research on "Rewiring the Brain: A Review on Innovations in Brain-Computer Interface for Stroke Rehabilitation" are as follows:

- ★ To review the current state of Brain-Computer Interface technologies that are applied in stroke rehabilitation, focusing on their mechanisms and therapeutic potential.

- ★ To identify what are the main technological innovations and improvements which have been made in BCI systems and have led to the best rehabilitation results in stroke survivors.
- ★ To identify major technological advancements and innovations in BCI systems that helped to improve rehabilitation outcomes for stroke survivors.
- ★ To explore the limitations and challenges of implementing BCI technology in clinical settings, including issues related to cost, patient variability, usability, and technological adaptability.
- ★ To give potential solutions or recommendations for overcoming the existing limitations of BCI technology and improving its accessibility and effectiveness in stroke rehabilitation.
- ★ To assess the likely future impact of BCI systems on changing conventional practices related to stroke rehabilitation and, perhaps most importantly, achieving positive changes in the quality of long-term patient outcomes.
